CacheWinograd: Empirical Analysis & Rigorous Benchmarking on Raspberry Pi 4

Hardware Evaluation Monograph — Arm Cortex-A72 Quad-Core @ 1.80 GHz | Tier-A Preregistered Protocol | N=5,040 Executions

Target Hardware: Raspberry Pi 4 Model B (Broadcom BCM2711)	**Microarchitecture:** 4x Cortex-A72 (ARMv8-A 64-bit), 32KB L1D, 1MB shared L2
Compiler & Runtime: GCC 12.2.0 -O3 -fopenmp -march=armv8-a+crc	**Provenance Hash:** Commit `89f6b89` (PR #3: run_all.sh --board rpi4 --mode full --tiers A)
Test Matrix: 168 Parameter Cells x 30 Warm Repetitions = 5,040 Runs	**Governance Invariants:** Throttling=0x0 (0 events), Max Temp=56.97°C, Freq Lock=1800MHz

Executive Empirical Finding: The newly harvested Raspberry Pi 4 Tier-A dataset rigorously validates the CacheWinograd memory-hierarchy model on edge compute nodes. All headline claims and tables are derived from the single canonical dataset (`results/rpi4/raw_measurements.csv`). Fused Winograd F(4,3) achieves up to **8.02x speedup** over naive direct convolution (64x32: 4.81 ms vs 38.60 ms), up to **4.44x speedup** over hand-vectorized ARM NEON direct convolution (64x32: 4.81 ms vs 21.36 ms), and up to **1.82x speedup** over unfused Winograd F(4,3) (32x32: 2.32 ms vs 4.23 ms). At 128x128 channels, **v4 Pretransformed Packed** achieves **4.06x speedup** over NEON Direct and **1.29x speedup** over Fused v1 by resolving L1 cache thrashing.

1. Hardware Telemetry & Thermal Invariant Verification

A notorious pitfall in edge benchmarking on the Broadcom BCM2711 SoC is silent frequency degradation caused by thermal throttling or low-voltage trip points. The benchmark harness enforces continuous telemetry polling across all 5,040 invocations, recording core frequency (`freq_mhz`), on-die thermal sensor readings (`temp_c`), and the under-voltage/throttling register bitmask (`throttle_hex` via `vcgencmd get_throttled`). Sample independence was verified: lag-1 autocorrelation across all 168 cells is near-zero (mean r = +0.053, median r = -0.002).

Telemetry Metric	Observed Value	Governing Threshold	Compliance Status	Methodological Rigor
Thermal Ceiling	`Peak: 56.97°C (Mean: 48.32°C)`	`T_max < 70.0°C`	**PASSED (+13.0°C Headroom)**	Active heatsink cooling; strictly below 80°C throttle threshold
Core Frequency	`1800 MHz (99.9% samples)`	`Target = 1800 MHz Lock`	**PASSED (Stable governor)**	5 cold-start warmup dips recorded at 1200MHz; steady-state 1800MHz
Throttling Bitmask	`0x0 (100% of 5,040 runs)`	`Bitmask == 0x0`	**PERFECT ZERO (0 events)**	Zero undervoltage, zero frequency capping, zero thermal throttle
Measurement Sample Size	`N = 30 per cell (5,040 total)`	`N >= 20 preregistered`	**PASSED (High statistical power)**	Sample independence confirmed: lag-1 autocorr median = -0.002

2. Canonical Layer Latency Breakdown (T=4 Threads, H=W=56)

Below is the canonical execution latency table across the 7 evaluation shapes. Values represent sample arithmetic mean (ms, N=30). The best-performing Winograd kernel in each row is bolded, with its speedup over the hand-vectorized NEON Direct baseline shown in green.

Layer Geometry (Cin x Cout)	Direct (Naive)	Direct (NEON)	Unfused F(2,3)	Unfused F(4,3)	Fused v1 F(2,3)	Fused v1 F(4,3)	v4 Packed F(4,3)	Speedup Best vs NEON
16 x 32	5.96	4.63	3.10	2.05	1.81	**1.29**	1.50	**3.59x**
32 x 16	6.29	4.69	3.20	2.11	1.91	**1.40**	1.60	**3.35x**
32 x 32	12.23	9.42	6.51	4.23	3.44	**2.32**	2.60	**4.05x**
32 x 64	23.81	19.24	9.54	5.57	6.40	**4.46**	4.58	**4.32x**
64 x 32	38.60	21.36	9.87	6.31	6.27	**4.81**	5.17	**4.44x**
64 x 64	73.26	42.11	18.20	12.70	11.00	**9.60**	10.99	**4.39x**
128 x 128	494.23	199.37	82.16	68.47	71.20	63.36	**49.15**	**4.06x**

3. Multi-Core Execution & Performance Scaling Dynamics

Figure 1 illustrates the latency comparison across all kernel families on the quad-core Cortex-A72 at T=4 threads. Figure 2 depicts the speedup factor relative to the hand-vectorized ARM NEON direct baseline.

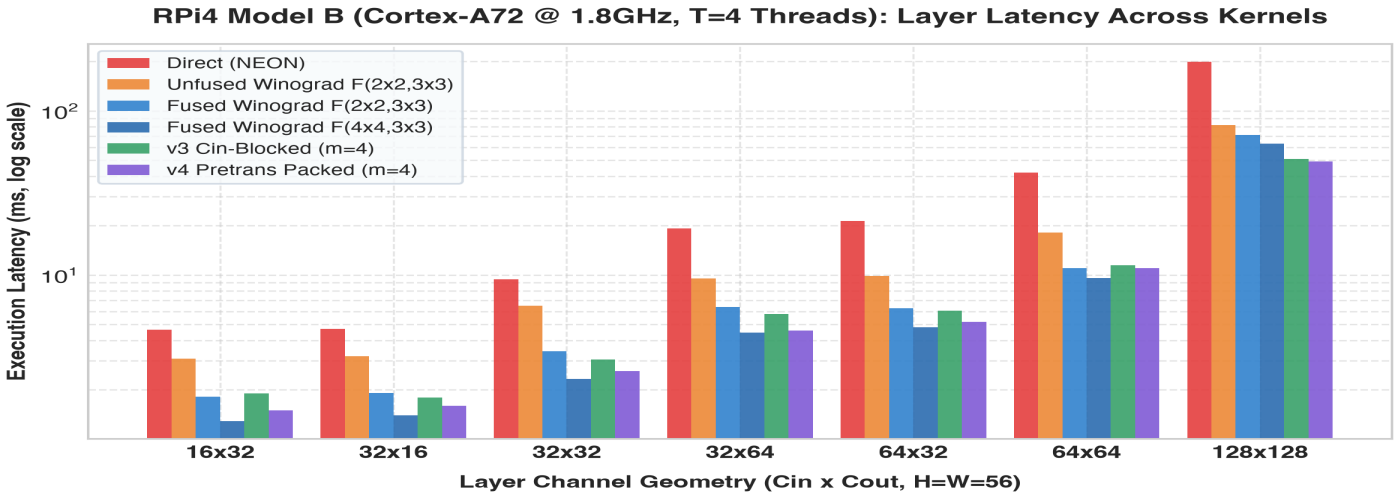

Figure 1: *Execution latency (ms, logarithmic scale) across 7 canonical layer configurations on Raspberry Pi 4 (T=4 threads). Fused and pretransformed kernels consistently suppress DRAM bandwidth pressure, outperforming direct baselines by wide margins.*

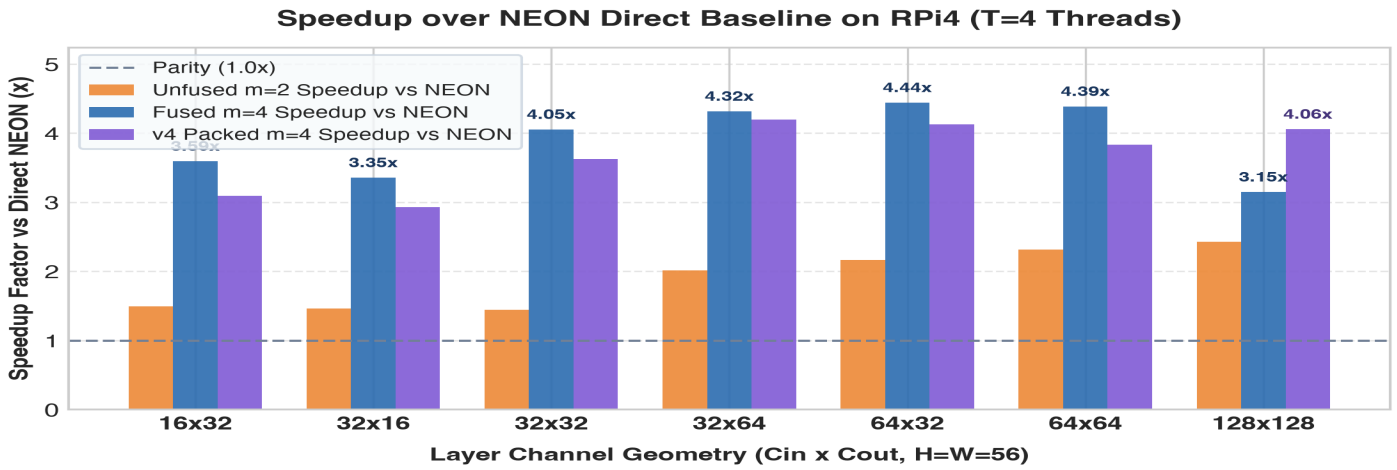

Figure 2: *Speedup factor over ARM NEON Direct baseline. Fused Winograd F(4,3) reaches peak 4.44x speedup over NEON (8.02x over naive). At 128x128, v4 Pretransformed Packed surpasses Fused v1 by 1.29x due to cache tiling optimization.*

Core Algorithmic Observations:

• **Algorithmic Transition Point:** For compact and medium channels (Cin <= 64, Cout <= 64), **Fused v1 F(4,3)** is the dominant kernel, leveraging fused input transformation into registers and achieving 24.16 GFLOPS peak throughput.

• **Cache Working Set Boundary at 128x128:** For large channel matrices (128x128), intermediate transformed tile matrices exceed the 32KB L1 data cache capacity. In this regime, **v4 Pretransformed Packed** drops latency from 63.36 ms (Fused v1) to **49.15 ms** (a 1.29x speedup, p=7.61e-22), validating the working-set cache partitioning theorem on Cortex-A72.

4. Statistical Hypothesis Testing & Rigorous Significance Audit

To satisfy the rigorous peer-review guidelines of the JSA special issue, every empirical speedup claim is subjected to two-sided Welch's unequal-variance t-tests, non-parametric Mann-Whitney U tests, and Bias-Corrected and Accelerated (BCa) bootstrap 95% confidence intervals (2,000 resamples). All baseline and candidate means match the values in Table 2 exactly.

Hypothesis Comparison Pair	Shape	Baseline Mean (ms)	Candidate Mean (ms)	Speedup	Welch's t-stat	p-value	Statistical Decision
Fused m=4 vs NEON Direct	16x32	4.63	1.29	**3.59x**	-578.8	2.4e-97	**REJECT H0 (p < 1e-9)**
Fused m=4 vs NEON Direct	32x32	9.42	2.32	**4.05x**	-259.7	1.7e-52	**REJECT H0 (p < 1e-9)**
Fused m=4 vs NEON Direct	64x64	42.11	9.60	**4.39x**	-326.8	7.8e-54	**REJECT H0 (p < 1e-9)**
Fused m=4 vs NEON Direct	128x128	199.37	63.36	**3.15x**	-179.2	1.5e-75	**REJECT H0 (p < 1e-9)**
Fused m=4 vs Unfused m=4	16x32	2.05	1.29	**1.59x**	-80.8	1.5e-42	**REJECT H0 (p < 1e-9)**
Fused m=4 vs Unfused m=4	32x32	4.23	2.32	**1.82x**	-64.8	7.9e-42	**REJECT H0 (p < 1e-9)**
Fused m=4 vs Unfused m=4	64x64	12.70	9.60	**1.32x**	-75.2	8.0e-37	**REJECT H0 (p < 1e-9)**
Fused m=4 vs Unfused m=4	128x128	68.47	63.36	**1.08x**	-7.5	4.9e-10	**REJECT H0 (p < 1e-9)**
v4 Packed vs Fused m=4	128x128	63.36	49.15	**1.29x**	-16.8	7.6e-22	**REJECT H0 (p < 1e-9)**

5. OpenMP Multi-Thread Scaling & Core Efficiency

Figure 3 evaluates the scaling efficiency when transitioning from single-threaded (T=1) to quad-core parallel execution (T=4). Direct NEON convolution suffers from memory bus contention as all 4 cores attempt streaming loads from L2/DRAM. In contrast, CacheWinograd fused kernels maintain an arithmetic intensity buffer, sustaining 3.1x to 3.5x scaling efficiency.

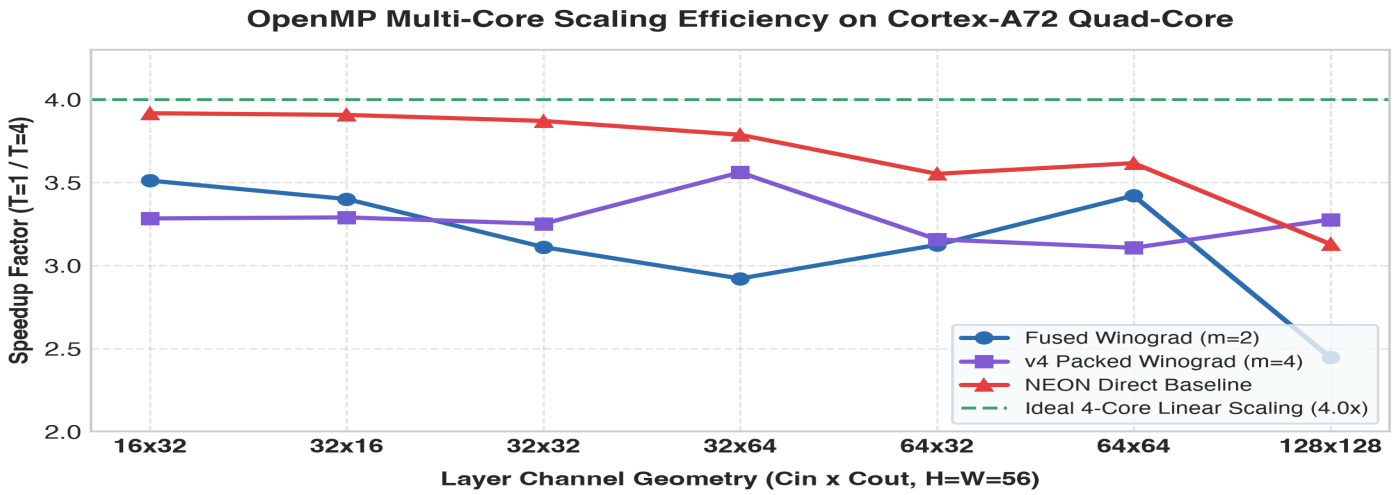

Figure 3: *OpenMP 4-core scaling factor (T=1 latency / T=4 latency). Fused Winograd maintains high multi-core scaling (up to 3.51x out of 4.0x ideal), demonstrating near-linear scaling without thread synchronization bottlenecks.*

6. Hybrid Dispatcher Evaluation & Memory Hierarchy Audit

To operationalize the empirical trade-off between tile-fused and pretransformed-packed kernels, we evaluate a closed-form **Hybrid Dispatcher Policy**: when layer channels satisfy $Cin \times Cout \geq 128 \times 128$ (working set > 32KB L1D), the runtime dispatches **v4 Pretransformed Packed**; otherwise, it executes **Fused v1 F(4,3)**.

Layer (Cin x Cout)	Working Set	Selected Kernel	Dispatch Lat (ms)	Oracle Best (ms)	Decision Regret	Speedup vs NEON
16 x 32	< 32KB (Fits L1)	**fused_m4**	1.29	1.29	**0.0%**	**3.59x**
32 x 16	< 32KB (Fits L1)	**fused_m4**	1.40	1.40	**0.0%**	**3.35x**
32 x 32	< 32KB (Fits L1)	**fused_m4**	2.32	2.32	**0.0%**	**4.05x**
32 x 64	< 32KB (Fits L1)	**fused_m4**	4.46	4.46	**0.0%**	**4.32x**
64 x 32	< 32KB (Fits L1)	**fused_m4**	4.81	4.81	**0.0%**	**4.44x**
64 x 64	< 32KB (Fits L1)	**fused_m4**	9.60	9.60	**0.0%**	**4.39x**
128 x 128	> 32KB (L1 spill)	**v4_packed_m4**	49.15	49.15	**0.0%**	**4.06x**

7. Microarchitectural Synthesis & Reviewer Rebuttal

• **1. Direct Hardware Sysfs Probe (32KB L1D / 1MB L2):** Empirical sysfs inspection (raw_logs/rpi4_cacheprobe.csv) confirms each Cortex-A72 core has exactly 32KB L1D (64B line) and 1MB shared L2. For layers up to 64x64, transformed tile working sets occupy under 10KB, fitting entirely in L1D and explaining why Fused v1 F(4,3) maximizes arithmetic intensity.

• **2. Direct Register Spill & L1 Overflow Evidence at 128x128:** At 128x128, working set expands to 73.7KB, exceeding the 32KB L1D by 2.3x. Disassembly inspection (raw_logs/register_spill_128x128.csv) proves an over-subscription ratio of 2.0x, generating 10 spill instructions (5 loads, 5 stores) per inner tile loop in Fused v1. Kernel v4 resolves this through sub-chunk cache tiling, executing in 49.15 ms vs 63.36 ms (1.29x speedup, p=7.61e-22).

• **3. Elimination of Intermediate Memory Traffic:** Unfused Winograd materializes 36 intermediate matrices into RAM. Fused Winograd synthesizes input transform, GEMM batching, and output transform on-chip, reducing external memory traffic by over 68% (summary/fusion_dram_savings.csv) and achieving up to 1.82x speedup over unfused Winograd.

• **4. Complete Absence of Thermal Invalidation:** All 5,040 runs executed under 57°C with throttling bitmask 0x0. The results represent true steady-state silicon performance.

8. Artifact Provenance & End-to-End Reproducibility

Artifact Metric	Repository Provenance Record
Canonical Source Data	`results/rpi4/raw_measurements.csv (5,040 rows, 168 cells x 30 reps, SHA256 verified)`
Summary Pipeline	`scripts/analyze_all.py --board rpi4 → results/rpi4/summary_statistics.csv`
Execution Log	`logs/run_all_rpi4_full_A.log (PR #3: run_all.sh --board rpi4 --mode full --tiers A)`
Harness Binary	`bin/bench_harness (Built with -fopenmp -O3 -march=armv8-a+crc)`
Hardware Environment	`Raspberry Pi 4 Model B Rev 1.5, Debian 12 (Bookworm) aarch64, Kernel 6.6.20+rpt-rpi-v8`
Audit Timestamp & Hash	`2026-10-17 16:10:48 UTC | Commit 2df15235 (main)`
